ABSTRACT

The weight, volume, and physical properties of trees 1 to 20 inches d.b.h. were determined for basswood, blackgum (upland), red maple, yellow-poplar, white oak, sweet birch, black locust, hickory, black oak, chestnut oak, northern red oak, scarlet oak, and white oak in the Southern Appalachian Mountains. Hard hardwoods, soft hardwoods, and individual species equations are presented for predicting green and dry weight and green volume of the total tree above-stump and its components by using d.b.h. and total height, d.b.h. and height to a 4-inch top, d.b.h. and saw-log merchantable height, and d.b.h. alone. Average specific gravity, moisture content, and weight per cubic foot of wood, bark, and wood and bark combined are presented for each species by tree size class and component. Bark percentage is also presented for each species by tree size class and component.

Keywords: Biomass, equations, specific gravity, moisture content, bark percentage, weight per cubic foot.

The hardwood forests of the Southern Appalachian Mountains can contribute significantly to supplies of solid wood, fiber, and energy wood through improved utilization and forest management. Few data, however, exist on the weight, volume, and physical properties of the total tree and its components for hardwood species of this region.

To meet this need, the USDA Forest Service collected tree weight and volume data for the important hardwood species growing in this region. These data were used to develop equations for estimating the weight and volume of individual trees and tree components. The specific gravity, moisture content, and bark content of the trees sampled were also determined.

This Paper presents green volume and green and dry weight equations for the total tree and tree components of 13 species--basswood (Tilia americana L.), upland blackgum (Nyssa sylvatica Marsh.), red maple (Acer rubrum L.), yellow-poplar (Liriodendron tulipifera L.), white ash (Fraxinus americana L.), sweet birch (Betula lenta L.), black locust (Robinia pseudoacacia L.), hickory species (Carya spp.), black oak (Quercus velutina Lam.), chestnut oak (Q. prinus L.), northern red oak (Q. rubra L.), scarlet oak (Q. coccinea Muenchh.), and white oak (Q. alba L.). Equations were developed from tree data collected in the Southern Appalachian Mountains of western North Carolina and northeastern Georgia. These species account for more than 85 percent of the commercial hardwood volume in this region. Equations were also developed for the combined hard hardwoods, combined soft hardwoods, and all 13 species.

Equations are given for estimating the weight and volume of wood and bark and wood only in the total tree, total stem, and the saw-log component of the stem. Ratio equations are also included for estimating saw-log stem weight or volume to any specified top diameter outside bark (d.o.b.). Wood and bark specific gravity, moisture content, bark content, and green weight per cubic foot are presented for the total tree and its components, by species and tree size classes.

Procedure

Field

Trees were selected from fully stocked, uneven-aged hardwood stands on the Chattahoochee National Forest in Georgia and the Pisgah and Nantahala National Forests in North Carolina. A stratified random sample of three to five trees per 2-inch d.b.h. class was selected at each sample location. Sample trees generally ranged from 5 to 20 or 22 inches d.b.h. Means and ranges in age and tree dimensions measured are shown in table 1 for each species and species group sampled. Stump height averaged 0.5 foot for trees 5.0 to 10.9 inches d.b.h. and 0.6 foot for trees > 11.0 inches d.b.h. Form class of the sawtimber-size trees (> 11.0 inches d.b.h.) ranged from 64 to 91 and averaged 80 for the soft hardwoods, and ranged from 61 to 90 and averaged 78 for the hard hardwoods.

Each tree was felled and measured for d.o.b. at 4-foot intervals up the stem. Total height, and height to the saw-log top, 9-, 4-, and 2-inch d.o.b., and base of full live crown were also recorded. Cross-sectional disks of wood and bark were removed from the stem and branches of sample trees for laboratory determination of specific gravity, moisture content, bark percentage, energy value, and nutrient concentration. In all trees > 5.0 inches d.b.h. except sawtimber-quality trees (> 11.0 inches d.b.h. with a minimum of one 16-foot grade 3 log), disks were cut at the butt, d.b.h., and quarter-points to the 4-inch d.o.b. top and at the 2-inch top. In sawtimber trees, disks were removed at the butt, at each saw-log bucking point, and at the stem location where d.o.b. measured 9, 4, and 2 inches.

The branches of each tree were cut from the stem and weighed in four size categories: extra large (> 4.0 inches d.o.b.), large (2.0 to 3.9 inches d.o.b.), medium (0.6 to 1.9 inches d.o.b.), and small (< 0.5 inch d.o.b.). Three cross-sectional disks were cut from randomly selected branches in each size category for analysis in the laboratory.

The stem of each tree was weighed by components (saw logs, pulpwood, and topwood) and the branches of each tree were weighted by size category.

Laboratory

Specific gravity was computed on green volume and ovendry weight. Moisture content was computed on ovendry weight after samples were dried to a constant weight at 215 °F. Percentage of bark was determined from disks and based on the green weight of sample disks. Moisture content, specific gravity, and percentage of bark in stem, branches, and total tree were calculated by weighting disk values in proportion to the volume of the component they represented. Weighted values for moisture content were used to convert component green weights to ovendry weight.

By using species diameter inside bark (d.i.b.) prediction equations, developed from d.o.b. and d.i.b. stem disk measurements, and the d.o.b. and height measurements taken at 4-foot intervals up the stem of each tree, the volume of wood in the stem to the saw log 9-inch, 4-inch, 2-inch, and tip were calculated by Smalian's formula. Green weight per cubic foot of stem bark and of branch wood and bark were calculated from weighted values for specific gravity and moisture content with the equation:

$$\text{Green weight per cubic foot} = [1 + \frac{MC}{100}] \cdot (SG) \cdot (C) \quad (1)$$

where: MC = weighted moisture content in percent
 SG = weighted specific gravity
 C = 62.4 pounds (weight of water per cubic foot)

Cubic-foot volume of stem bark and branch wood and bark were computed by dividing green component weight by its green weight per cubic foot. Cubic-foot volume of stem wood and bark combined was computed by adding the volume of bark to the volume of wood.

Analysis

Regression equations were developed to predict green and dry weight and green volume of wood and bark in the total tree above stump, stem from butt to tip, and saw-log stem. Independent variables were: diameter at breast height (D), total height (Th), saw-log merchantable height (Mh), and height to a 4-inch d.o.b. top (H4).

A logarithmic transformation (base 10) was used to obtain a relatively homogeneous variance, which is assumed in regression analysis. Two equations were developed for the d.b.h., d.b.h. and total height, and d.b.h. and height to 4-inch top--one for trees < 11.0 inches d.b.h. and one for trees \geq 11.0 inches d.b.h. The 11-inch point was not the optimum point to shift from one equation to the other for all species or tree components, but it was the most desirable from a practical standpoint. Hardwood trees < 11 inches in diameter are classified as sapling or poletimber, and trees \geq 11 inches are classified as sawtimber. The procedure outlined in Draper and Smith (1981) for fitting two linear equations with a known point of intersection was used to develop the following equations:

$$\log Y_p = a + b \log X + E \quad (2)$$

$$\log Y_s = a + b \log (11^2 H) + c \log (D^2 / 11^2) + E \quad (3)$$

where: Y_p = predicted component weight or volume for trees
 < 11.0 inches d.b.h.

Y_s = predicted component weight or volume for trees
 \geq 11.0 inches d.b.h.

X = D², D²Th or D²H4

H = Th or H4

D = d.b.h.

E = experimental error

a,b,c = regression coefficients

The following model was used for developing regression equations based on d.b.h. and saw-log merchantable height:

$$\log Y = a + b \log X_1 + c \log X_2 + E \quad (4)$$

where: Y = predicted component weight or volume

$$X_1 = D^2$$

$$X_2 = Mh$$

E = experimental error

a, b, c = regression coefficients

When logarithmic estimates are converted back to original units, they are biased downward because the antilogarithm of an estimated mean gives the geometric rather than the arithmetic mean (Cunia 1964). To adjust for this bias, a correction factor was computed and applied to each model by using Baskerville's (1972) procedure. The final equations, including correction factors, were:

$$Y = 10^a + b \log (D^2) + c \log (Mh) + (S_{y,x}^2 \log_e 10)/2 \quad (5)$$

$$Y_p = 10^a + b \log (D^2H) + (S_{y,x}^2 \log_e 10)/2 \quad (6)$$

$$Y_s = 10^a + b \log_{10} (11^2H) + c \log (D^2/11^2) + (S_{y,x}^2 \log_e 10)/2 \quad (7)$$

Equations (5), (6), and (7) can be simplified to:

$$Y = a' (D^2)^b (Mh)^c \quad (8)$$

$$Y_p = a' (D^2H)^b \quad (9)$$

$$Y_s = a'' (D^2)^b (H)^c \quad (10)$$

where: $a' = 10^a + (S_{y,x}^2 \log_e 10)/2$

$$a'' = a' (11^2)^b - c$$

$S_{y,x}^2$ = error mean square from regression analysis

Comparison of average deviations (actual minus predicted) by d.b.h. classes and the sums of the squared deviations for the single log-log equation and segmented log-log equation showed that segmented log-log equations (9) and (10) gave the best results for the d.b.h., d.b.h. and total height, and d.b.h. and height to 4-inch top independent variable combinations (Clark and others 1985). Equations (9) and (10) are more complex than a single equation, but the improved accuracy justified their use.

The following exponential ratio equation was used to estimate the proportion of predicted total-stem weight or volume to a specified top d.o.b.:

$$Y_R = e^a (D^b D^c) \quad (11)$$

where: Y_R = ratio of stem weight or volume to top d.o.b. to
predicted total stem

d = specified stem top diameter in inches

D = tree diameter at breast height in inches

a,b,c = regression coefficients

e = base of natural log = 2.71828

The exponential ratio model shown below was developed to estimate a ratio for expanding saw-log stem weight or volume to any d.o.b. top above the saw-log top.

$$Y_R = e^a \left[(Mh)^b ((1 - (\frac{d}{.78D})^2)^2)^c \right] \quad (12)$$

where: Y_R = ratio of stem weight or volume to top d.o.b. to
saw-log stem

Mh = saw-log merchantable height in feet

d = specified top diameter in inches

D = tree diameter at breast height in inches

.78 = constant based on average form class

a,b,c = regression coefficients

e = base of natural log

Results

Physical Properties of Sample Trees

The average specific gravity of wood and bark by tree component is shown in table 2 for individual species, soft hardwoods, hard hardwoods, and all trees combined. The average total-tree wood specific gravity of the soft hardwood species was 0.439 for poletimber (5.0 to 10.9 inches) and 0.440 for sawtimber (> 11.0 inches d.b.h.) compared with hard hardwood species, which averaged 0.598 for poletimber and 0.604 for sawtimber. Basswood had the lowest average total-tree wood specific gravity and blackgum the highest for the soft hardwoods group. In the hard hardwoods group, sweet birch had the lowest average total-tree wood specific gravity and hickory had the highest.

The average moisture content of wood and bark by tree component and size class is shown in table 3 for the species and species groups sampled. Total-tree wood moisture content for the soft hardwoods averaged 105 percent for poletimber and 99 percent for sawtimber compared with hard hardwoods, which averaged 62 percent for poletimber and 67 percent for sawtimber. In the soft hardwoods group, basswood had the highest average total-tree moisture content compared with red maple, which had the lowest. In the hard hardwoods group, white oak had the lowest total-tree wood moisture content and northern red oak had the highest.

Table 4 shows the average proportion of bark in the tree, based on green weight of wood and bark, by tree component and size class for the species sampled.

Basswood had the highest bark percentage of the soft hardwoods and chestnut oak had the highest for the hard hardwoods. The percentage of stem weight in bark increased as stem d.o.b. decreased. Thus, poletimber trees generally had a higher proportion of the green weight in bark than did sawtimber trees, and branches had the highest proportion of green weight in bark.

The average green weight per cubic foot of wood, bark, and wood and bark combined, by tree component, for poletimber and sawtimber are shown in table 5. Because of the soft hardwood and hard hardwood species grouping, the average range of green weight for cubic foot of wood for the two groups is similar--49 to 67 pounds for the soft hardwoods and 52 to 67 pounds for the hard hardwoods. This is caused by the relatively high moisture content and specific gravity of blackgum in the soft hardwoods group and the low moisture content of white ash in the hard hardwoods group. The average green weight per cubic foot of wood for the soft hardwood species was 56 pounds for poletimber and 54 pounds for sawtimber compared with 62 pounds for pole and sawtimber hard hardwoods.

The average green weight of wood and bark per cubic foot of wood by tree component for poletimber and sawtimber-size trees is shown in table 6. The weight of wood and bark per cubic-foot volume of wood is a useful factor for estimating the volume of wood in a tree or its components when weight of wood and bark is known or for estimating green weight of wood and bark when volume of wood is known. The green weight of wood and bark per cubic foot of wood for the total tree averaged 68 pounds for poletimber and 65 pounds for sawtimber soft hardwoods compared with 75 pounds for poletimber and sawtimber hard hardwoods.

The average green weight of wood and bark per cubic foot of wood was highest for branches and decreased with increasing stem diameter (table 6).

Prediction Equations

A series of equations was developed to predict total-tree and tree component weight and volume for each species, the soft hardwood and hard hardwood groups, and all species combined. Equations were developed for predicting the green and dry weight of wood and bark combined and wood alone in the above-stump total tree. Stem equations were developed for estimating the green and dry weight of wood and bark combined, and wood alone for the total stem. Volume equations were also developed for wood and bark combined and wood alone in the above-stump total tree and total stem.

Since tree height is measured to different top limits by various organizations, equations were developed by using diameter (D) alone and in combination with total height (Th), height to 4-inch top ($H4$), and merchantable height (Mh) as independent variables. Equation (9) was used to estimate the weight and volume of the total tree and stem for trees 5.0 to 10.9 inches d.b.h., and equation (10) was used for trees > 11.0 inches d.b.h. when D alone, D and Th , or D and $H4$ were the independent variables.

Equation (8) was used to estimate weight and volume of the total tree and saw-log merchantable stem for trees > 11.0 inches d.b.h. when D and Mh were the independent variables. Equations based on D and Mh were developed only for species sampled sufficiently in the sawtimber diameter classes. Equations were developed for the soft hardwoods, hard hardwoods, and all species, and for yellow-poplar, white oak, hickory, black oak, chestnut oak, northern red oak, scarlet oak, and white oak.

Equation (11) was used to estimate the proportion of total-stem weight or volume in the stem to any d.o.b. top when stem weight or volume was estimated with D, D and Th, or D and H4 as the independent variables. Equation (12) was used to estimate a ratio for expanding estimated saw-log merchantable-stem weight or volume to any d.o.b. top above the saw-log top when U and Mh were the independent variables.

Equations that use D with Th or D with H4 fit the existing total-tree and total-stem weight and volume data well, based on the criteria of mean square error and absolute deviation of observed from predicted. Equations that use D and Mh fit existing saw-log merchantable-stem weight and volume data well. When average tree height and stem taper are similar to those of our sample trees, the equations with U alone will result in good estimates of the tree weight and volume. When average tree height by d.b.h. class are different from the sample trees, however, the equations that include a height variable should be applied directly or used to develop local weight-volume tables based on D alone.

Regression coefficients for estimating weight and volume are listed below, by independent variable and table number:

<u>Independent variable</u>	<u>Weight</u>	<u>Volume</u>
D alone	tables 7, 8	tables 9, 10
D and Th	tables 11, 12	tables 13, 14
D and H4	tables 15, 16	tables 17, 18
D and Mh	tables 19, 20	tables 21, 22

In addition to the regression coefficients, tables 7 through 22 contain the coefficients of determination and standard error (\log_{10}) for each equation.

Regression coefficients for estimating the proportion of the total-stem weight and volume in the stem to a specified d.o.b. top are given in tables 23 and 24. Table 23 contains coefficients for estimating ratios for stem green and dry weight of wood and bark combined and wood only, and table 24 contains the coefficients for stem volume of wood and bark combined and wood alone. Equation coefficients for expanding estimated saw-log merchantable-stem weight and volume are shown in tables 25 and 26, respectively.

How to Use Prediction Equations

The following examples illustrate how to use the equations in tables 7 through 26 to estimate the weight or volume of the total tree and its components.

This tabulation presents the tree data needed to estimate weight and volume when d.b.h. and Th are measured and equations (9) and (10) are used:

Example of trees < 11.0 inches d.b.h.

D = 10.0 inches

Th = 70 feet

Example of trees \geq 11.0 inches

$$D = 14.0 \text{ inches}$$

$$Th = 90 \text{ feet}$$

To estimate total-stem wood and bark green weight (Y_{STEMWB}) of a soft hardwood with these dimensions, the following equations would be selected from table 12 and solved as follows:

Trees < 11.0 inches d.b.h.--use equation (9)

$$\begin{aligned} Y_{STEMWB} &= a^* (D^2 Th)^b \\ &= 0.19934 ((10^2) (70))^{0.94973} \\ &= 0.19934 (7000)^{0.94973} \\ &= 0.19934 (4,485.44) \end{aligned}$$

$$Y_{STEMWB} = 894 \text{ pounds}$$

Trees ≥ 11 inches,,d.b.h.--use equation (10)

$$\begin{aligned} Y_{STEMWB} &= a'' (D^2)^b (Th)^c \\ &= 0.16133 (14^2)^{0.99384} (90)^{0.94973} \\ &= 0.16133 (196)^{0.99384} (90)^{0.94973} \\ &= 0.16133 (189.73) (71.78) \end{aligned}$$

$$Y_{STEMWB} = 2,197 \text{ pounds}$$

The same mathematical procedure shown above would be used to solve equations (9) or (10) for any of the tree component equations in tables 7 through 22.

To estimate the proportion of total-stem green weight of wood and bark in the stem of a 10-inch d.b.h. tree to a 4-inch d.o.b. top (Y_R), the following soft hardwood ratio regression coefficients would be selected from table 23 and solved by using equation (11) as shown below. The same equation is used for all size trees.

$$Y_R = e^a (d)^b (D)^c$$

$$= 2.71828 \left[-2.21340 (4)^{3.69663} (10)^{-4.00754} \right]$$

$$= 2.71828 \left[-2.21340 (168.11) (0.000098) \right]$$

$$= 2.71828^{-0.03647}$$

$$Y_R = 0.964$$

$$\begin{aligned}\text{Stem weight to 4-inch top} &= (Y_{\text{STEMWB}}) (Y_R) \\ &= 894 (0.964)\end{aligned}$$

Stem weight to 4-inch top = 862 pounds

The procedure shown above can be used to estimate the proportion of total stem in the stem to any d.o.b. top by substituting for d in equation (11).

The following tabulation shows the tree data needed to estimate weights and volumes when d.b.h. and M_h are measured and equation (8) is used.

$$D = 14.0 \text{ inches d.b.h.}$$

$$M_h = 2.0 \text{ logs}$$

To use equation (8), M_h must be in feet, thus:

$$M_h = 33.1 \text{ feet} = (2.0 \text{ logs}) (16.3 \text{ ft/log}) + (0.5 \text{ ft for stump})$$

To estimate the green weight of wood and bark in the saw-log merchantable stem (Y_{SAWWB}) of a soft, hardwood tree, by using equation (8) the following coefficients would be selected from table 20 and solved as follows:

$$\begin{aligned}Y_{\text{SAWWB}} &= a^b (D^2)^c (M_h)^d \\ &= 0.55968 (14^2)^{0.97608} (33.1)^{0.76439} \\ &= 0.55968 (172.75) (14.51)\end{aligned}$$

$$Y_{\text{SAWWB}} = 1,403 \text{ pounds}$$

The same mathematical procedure shown above would be used to solve equation (8) for any sawtimber tree component equation in tables 19 through 22.

To estimate a ratio (Y_R) for expanding estimated saw-log merchantable-stem green weight of wood and bark of the previous tree to weight to a 4-inch d.o.b. top, the following soft hardwood ratio equation would be selected from table 25 and solved by using equation (12) as shown below:

$$\begin{aligned}Y_R &= e^a \left[(M_h)^b ((1 - (\frac{d}{.78D})^2)^2)^c \right] \\ &= 2.71828^{20.03667} \left[(33.1)^{-1.15011} ((1 - (\frac{4}{.78(14)})^2)^2)^{0.30738} \right] \\ &= 2.71828^{20.03667} (0.01787) (0.91524) \\ &= 2.71828^{0.32764} \\ Y_R &= 1.388\end{aligned}$$

$$\begin{aligned}\text{Stem weight to 4-inch top} &= (Y_{SAWWB}) (Y_R) \\ &= 1,403 (1.388)\end{aligned}$$

Stem weight to 4-inch top = 1,947 pounds

The tree components predicted by using the equations provided can be used to calculate additional tree components. For example, to estimate the weight or volume of the crown (branches and topwood) subtract estimated weight of the stem to a specified d.o.b. top from total-tree weight of wood and bark. The weight or volume of bark alone can also be estimated by subtracting component weight or volume of wood from wood and bark.

Similar-size trees may vary in weight and volume because of differences in crown size, stem taper, and weight per cubic foot. Therefore, these equations should be applied only to trees growing in natural, fully stocked stands with tree dimensions and weight per cubic foot similar to the tree sampled.

Y_R = ratio of stem weight or volume to top d.o.b. to saw-log stem

Mh = saw-log merchantable height in feet

d = specified top diameter in inches

D = tree diameter at breast height in inches

.78 = constant based on average form class

a,b,c = regression coefficients

e = base of natural log

Table 26.--Regression coefficients for estimating stem volume to a specified d.o.b. top diameter as a proportion of the saw-log stem volume for hardwood species in the Southern Appalachian Mountains

Clark, Alexander, III; Schroeder, James G.
Weight, volume, and physical properties of major hardwood species
in the Southern Appalachian Mountains. Res. Pap. SE-253. Asheville,
NC: U.S. Department of Agriculture, Forest Service, Southeastern
Forest Experiment Station; 1985. 63 pp.

The weight, volume, and physical properties of trees 1 to 20 inches
d.b.h. were determined for basswood, blackgum (upland), red maple,
yellow-poplar, white oak, sweet birch, black locust, hickory, black oak,
chestnut oak, northern red oak, scarlet oak, and white oak in the
Southern Appalachian Mountains. Hard hardwoods, soft hardwoods, and
individual species equations are presented for predicting green and dry
weight and green volume of the total tree above-stump and its components
by using d.b.h. and total height, d.b.h. and height to a 4-inch top,
d.b.h. and total height, d.b.h. and height to a 4-inch top,
d.b.h. and saw-log merchantable height, and d.b.h. alone. Average
specific gravity, moisture content, and weight per cubic foot of wood,
hark, and wood and hark combined are presented for each species by tree
size class and component. Bark percentage is also presented for each
species by tree size class and component.

Keywords: Biomass, equations, specific gravity, moisture content,
hark percentage, weight per cubic foot.

The Forest Service, U.S. Department of Agriculture, is dedicated to the principle of multiple use management of the Nation's forest resources for sustained yields of wood, water, forage, wildlife, and recreation. Through forestry research, cooperation with the States and private forest owners, and management of the National Forests and National Grasslands, it strives—as directed by Congress—to provide increasingly greater service to a growing Nation.

USDA policy does not permit discrimination because of race, color, national origin, sex or religion. Any person who believes he or she has been discriminated against in any USDA-related activity should write immediately to the Secretary of Agriculture, Washington, D.C. 20250.
